

Peak Energy: Economic Decline, Food Security, and Cultural Stress

We are not going to run out of fossil fuels. .. Not ever.... Unfortunately: ... thats not the problem. We continue to consume fossil fuels without regard for the consequences. We assume our inherited good fortune of coal, oil and natural gas will go on forever. But are there limits to growth? Yes. And we shall encounter these limits in the 21st century. Our energy challenges will become painfully evident before 2050.

There isnt enough fossil energy left on this planet to ensure the economic prosperity of 9.4 billion people. And that is the problem.

Our intensive consumption of energy is not sustainable. Continuing population growth simply increases the number of humans who will ultimately suffer. By any measure, we humans are living far beyond our means. Its inevitable. Our energy intensive infrastructure will collapse. The associated economic decline will cause political chaos. For those of us who live in an industrialized nation, the associated lifestyle change will be traumatic. This report is about the economic and cultural impact of fossil fuel depletion, with particular attention on the United States and by inference all first world (OECD) nations. The depletion of our resources is not a phenomenon that will happen sometime in the distant future. It is happening now. It has already altered the objectives and alliances of international diplomacy, empowered the political aspirations of producer nations, restructured how world markets work, and changed the economics of fossil fuel exploration, production, transportation and consumption. It is also increasing the price of gasoline, diesel, propane, jet, and heating oil fuels, along with electricity, fertilizer, soil amendmets, and thousands of other products. With 20 graphs and a no nonsense text - all based on a realistic analysis of published information - this report outlines the interaction of world energy consumption with global economic

challenges, population growth, fuel price trends, and fossil fuel consumption from 2012 through 2050. If this analysis is correct, peak energy will occur in 2037.

In order to help the reader understand the facts, I have included two popular essays with this report: [How Much Oil Do We Have Left? Really?](#) and [Twelve Criteria for Evaluating Our Energy Options](#) Read these texts and use them as a reference.
